

LEDs and Solar

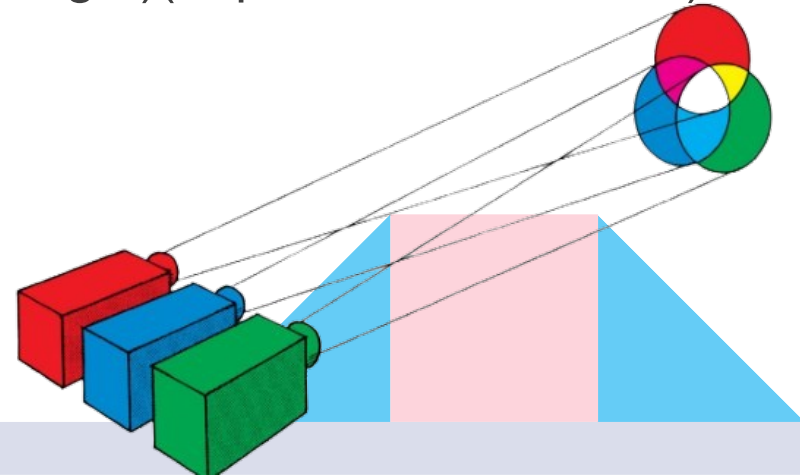

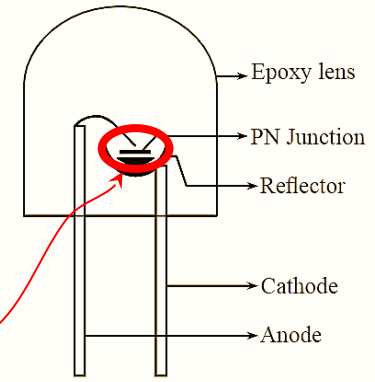

Power -

Relativity (110-

112)

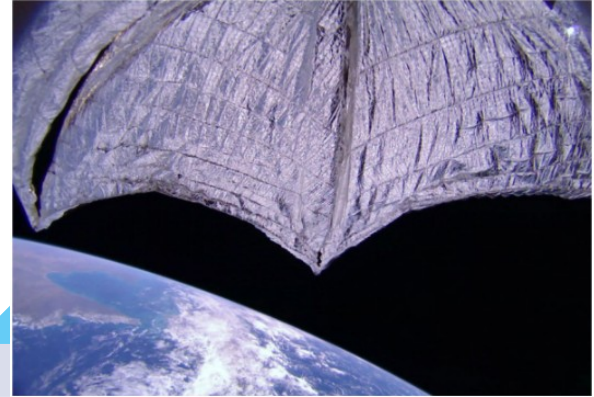

LEDs

- Incandescent mostly emits heat
- diode only lets current flow in 1 direction(AC→DC)
- Light emitting diode(LED)
 - Uses 2 semiconductors (bad conductors that get better together) & ext. voltage
 - Electrons move to outer shell(just emits light)(depends on materials)
- red→green → blue LEDs
- Way more efficient than incandescent

Solar Power

- Semiconductors absorb light, electrons move to conducting shell, current flows
 - Same things for IR in burglar alarms
- More use of solar panels & cheaper (could take over energy in 20230s)
- Most satellites are somewhat solar powered
- For now we use chemical rockets to go way far from earth
 - Maybe lightsail [catches sunlight to slowly move]
